

# New frameworks for equation of state and postprocessing

Wolfgang Kastaun<sup>1</sup>

<sup>1</sup>Trento University

ET Workshop, Stockholm, Aug. 2015

## PostCactus framework

- ▶ Access various Cactus data formats from Python
- ▶ Interactive or from scripts
- ▶ Can be used locally or remotely via IPython notebook server
- ▶ History: grown from pile of postprocessing scripts
- ▶ Download from public repository  
`hg clone ssh://hg@bitbucket.org/DrWhat/pycactuset`
- ▶ Rudimentary documentation (requires Sphinx)  
`cd PostCactus/doc`  
`make html`

# PostCactus framework

## Features

- ▶ Can read 1D,2D,3D hdf5 data (chunked, unchunked, multiple files)
- ▶ Resampling to uniform grids, dimensional cuts
- ▶ 1D ASCII data
- ▶ Scalars: min, max, norms, integrals
- ▶ Multipole data
- ▶ GW signal from  $\Psi_4$  multipoles or WaveExtract
- ▶ Combined BH information from AHFinderDirect and QuasiLocalMeasures/IsolatedHorizons
- ▶ Reads parfiles, transforms into Python objects
- ▶ Transparent merging of data from different restarts

# PostCactus framework

## Limitations

- ▶ Does not support one file per group hdf5 format
- ▶ Needs helper thorn to store grid volume to convert average to integral
- ▶ Parsing parfiles is a mess, and default parameters are inaccessible
- ▶ Need machine readable file with all parameters
- ▶ No interface for restarts for lack of well defined metadata
- ▶ No MPI support for postprocessing

# PostCactus framework

## Dependencies

- ▶ Python 2.7 (might change to Python 3)
- ▶ H5Py
- ▶ PyTables (soon replaced by H5Py)
- ▶ NumPy, SciPy

## Can be used with

- ▶ Ipython, Ipython notebook server
- ▶ Matplotlib
- ▶ Yt, MayaVi

## SimRep framework

- ▶ Automatic generation of html reports from simulation data
- ▶ Modular design, easy to design own report pages
- ▶ Python based document description language
- ▶ Can run arbitrary postprocessing scripts to get plots
- ▶ Available modules
  - ▶ Logfiles
  - ▶ Global quantities (total baryon mass, max density, lapse, ..)
  - ▶ Constraint violation
  - ▶ Performance (rudimentary, only memory and speed)
  - ▶ GW signal

## EOS framework

- ▶ Interfaces for barotropic  $P(\rho)$  and thermal  $P(\rho, \epsilon, Y_e)$  EOSs
- ▶ EOSs have validity range (important for con2prim)
- ▶ Consistent range checking
- ▶ Completely independent from Cactus (important for unit testing)
- ▶ Implemented barotropic EOSs: polytropic, piecewise polytropic, tabulated
- ▶ Implemented thermal EOSs: ideal gas, hybrid EOS
- ▶ Not public yet: tabulated thermal EOS

## EOS framework

- ▶ C++ EOS objects
- ▶ Clean separation between interface and implementation
- ▶ Implementation of particular EOS only needs to provide some virtual methods that define the EOS
- ▶ EOS objects can be copied without worrying about memory or ownership
- ▶ Uses reference counted pointer to implementation internally
- ▶ Cactus thorns to register global evolution and initial data EOSs
- ▶ Fortran wrappers possible
